## Abstract:

**Introduction:** Central nervous system tumors are rare; in 2015 they represented approximately 1.4% of new cancer diagnoses, causing 2.6% of deaths by cancer that year. In Colombia, there are few reports on the epidemiology of brain tumors, and those that exist are local databases that do not have a rigorous and massive registry. Due to limited epidemiological information in our country, this document aims to characterize the epidemiology of brain tumors in Colombia over a 10-year period.

**Methods:** A retrospective descriptive observational study was conducted, using databases of population-based cancer registries in Colombia. We extracted information from a 10-year period recorded in patients with tumors without age group restriction. A descriptive analysis was carried out for all the variables considered, the incidence and mortality rates per 100,000 person years were calculated. Statistical software Stata 14.0 was used.

**Results:** Our analysis was performed with a population of 775 adult patients and 123 pediatric patients, with an incidence of 1.55 per 100,000 individuals in the pediatric population and 3.19 per 100,000 individuals in the adult population. The mortality rate for pediatric and adult patients was 0.063 per 100,000 individuals and 1.86 per 100,000 individuals respectively. The most frequent tumors in the pediatric age group were neuroepithelial tumors, embryonal tumors and ependymal tumors, whereas for adults, the most frequent were neuroepithelial tumors, meningiomas and hematolymphoid tumors.

**Conclusions:** This study constitutes the most recent work on the epidemiology of brain tumors in Colombia. There was a clear general underreporting and statistics lower than those compared with the literature. It is intended to expand coverage and data collection in population-based cancer registries.

**Key words:** transnasal- trans; sphenoidal; elderly; hypopituitarism

## Introduction

Nervous system tumors are rare, and accounted for approximately 1.4% of the new cancer diagnoses in 2015 in the United States. These tumors caused 2.6% of cancer deaths in that year; they have a greater clinical involvement in children and young adults, and cause approximately 30% and 20% of cancer deaths, respectively [1–6]. Their prevalence decreases with age; these tumors are the first cause of neoplasm in the 0-14 year age group, and the third cause in the 15-39 year age group, preceded by breast and thyroid cancer, and are within the less common neoplasms in patients older than 40 years [1,7,8]. The most common central nervous system (CNS) tumors in pediatric age are pilocytic astrocytoma, embryonal

tumors and malignant gliomas, while meningiomas, pituitary tumors and malignant gliomas are found in adults [1–3,9–13].

CNS tumors represent a diagnostic and therapeutic challenge, because the differentiation between malignant and benign may be unclear. In addition, a complete surgical resection is not always achieved, which results in relapses, in an important compromise of the neurological function, and can be potentially fatal [14–18]. It is necessary to know their incidence, mortality and epidemiology, to implement health policies and diagnostic screening [19,20].

There are few reports on the disease burden of brain tumors in Colombia. This information is necessary in order to implement health policies, develop strategies to plan preventive activities, build capacities in the provision of health services, improve the quality of medical care and plan clinical trials [21,22]. This work aims to provide epidemiological information on brain tumors from a 10-year period, collected from population-based cancer registries in different cities of our country. This in order to generate knowledge and provide data to the actors involved in the social security system and to the health regulatory agencies, in order to create promotion actions, and to ensure prevention and early detection of brain tumors.

## Materials and Methods

A descriptive observational retrospective study was conducted, using databases of Colombian population-based cancer registries (RCBPs, by their Spanish acronym). Data were collected at the Cancer Information System in Colombia (SICC-infocancer, by its Spanish acronym) center, which collects general information on mortality and incidence from the cities of Bucaramanga, Pasto, Manizales and Barranquilla [23,24]. Attached is the individual population registry of Cali, Valle del Cauca, Colombia [25] and of international agencies (network of national cancer institutes, Ministry of Health, IARC/GLOBOCAN) [3,4]. Anonymised data from patients with brain tumors (malignant or benign) were obtained for the 2003-2012 period; this information was grouped without age-group restriction into 2 groups: pediatric (under 18 years old) and adults (older than or equal to 19 years old). The general population characteristics and the characterization of brain tumors were analyzed. The general mortality for each department of Colombia presented in SICC-Infocancer was calculated, but it was extracted from the DANE (National Administrative Department of Statistics). Averages of standardized mortality rates were obtained, grouped by 5 years (2003-2007 and 2008-2012); this was done for greater comfort when performing the analyzes, without affecting the reliability of the data due to the minimum variability during the 10-year period. On the other hand, since the registry covers the 2003-2012 period, the classification prior to the latest update proposed by the WHO in 2016 was used for the histological reference of the tumor subtypes.

## Statistical analysis

For the statistical analysis, a database with the collected data and raw information was created, and a descriptive statistical analysis was performed for all the variables considered in the analysis and for the selected subgroups. The Shapiro-Wilk test was applied to determine the normality of the data; data that followed a normal distribution are presented as average and standard deviation; categorical variables are presented in proportions or percentages. Incidence and mortalities are presented as relative frequencies, crude rates and age-adjusted rates (under 18 and over 18) expressed per 100,000 person-years; the standard population used was the world population according to SEGI, as is conventional to compare standardized rates using population-based cancer registry data [23]. The Stata 14.0 statistical program was used for the statistical analysis.

## Results

### Pediatric Central Nervous System Tumors

#### General demographic characteristics

During the 2003-2012 period, a total of 123 cases of brain tumors were reported in SICC-infocancer in the pediatric population. 53.7% of these cases corresponded to men, with an average age at the time of diagnosis of 8.4 years (SD: +- 5.43 years). Regarding their behavior, 95.1% were malignant, 3.3% of uncertain behavior and 1.6% were benign (**Table 1**).

#### Characterization of brain tumors

Malignant supratentorial tumors were the most common, which represented 63.4% (**Supplement 1**). According to the histological subgroup, the most common in ascending order were glial lesions, embryonal tumors and ependymal tumors, of which the predominant histological subtypes were astrocytoma, medulloblastoma and ependymoma (**Supplement 2**). Regarding their location, parenchymal tumors were the most common at supratentorial level, and of these, temporal and parietal lobe lesions were the most significant, followed by overlapping and ventricular lesions. On the other hand, cerebellar lesions were the most common site of infratentorial lesion localization (**Supplement 3**).

**Supplement 3:** Characterization of tumors of the pediatric population by location

### Incidencia and mortality

Incidence was similar between males and females in the different cities, being lower for the female population (*Table 2*). Regarding mortality, the crude and standardized rate was 0.12 and 0.06 per 100,000 population, respectively.

### **ADULT CENTRAL NERVOUS SYSTEM TUMORS**

### General characteristics

A total of 775 cases of brain tumors in adults were reported to SICC-infocancer. The average age of presentation was 52.7 years (SD: +-17.1 years), with an equitable distribution between genders. Overall, 92.1% of the tumors had a malignant behavior, 7% had a benign behavior, and 0.9% an uncertain behavior. The main basis of the diagnosis was histological, and represented 73.8% of the cases (*Table 1*).

Variable	Pediatric		Adults	
	n=123	%	n=775	%

**Table 1:** Sociodemographic characterization of the pediatric and adult population

Characterization of brain tumors

Overall, 92% of the tumors were supratentorial, 4% were infratentorial and 2% were hematolymphoid (Supplement 4). Glial lesions, meningiomas and hematolymphoid tumors were the most common histological types, with 82.4%, 8.9% and 2.3%, respectively (Supplement 5). Regarding supratentorial lesions, the temporal lobe was the most commonly compromised site (7.6%); and for infratentorial lesions, the

cerebellum was the most common site, with 22% of cases (Supplement 6).

Incidence and mortality

The incidence behaved similarly in different cities for both sexes (Table 2). Regarding mortality, the crude and standardized rate was 2.8 and 1.9 per 100,000 population, respectively.

Rates expressed per 100,000 person-years, SEGI standard population

**Table 2:** Incidence and mortality in the pediatric and adult population

## DISCUSSION

Data from 775 adult patients and 123 pediatric patients were obtained. Incidence and mortality in adults were 3.2 per 100,000 population and 1.9 per 100,000 population, respectively. Incidence and mortality in the pediatric population were 1.6 per 100,000 population and 0.06 per 100,000 population, respectively. In 2012, the worldwide age-adjusted incidence rate of primary malignant brain tumors and other CNS tumors using the global population standard was 3.4 per 100,000 population. Incidence rates were higher in more developed countries (5.1 per 100,000 population) than in less developed countries (3.0 per 100,000 population). In the United States, brain and other CNS tumors were the most common cancer site in people aged between 0-14 years, with an annual average age-adjusted incidence rate of 5.54 per 100,000 population; people over 40 years of age had an annual average age-adjusted incidence of 40.82 per 100,000 population [26].

When comparing these international data, the incidence rates observed in Colombia are low compared to those in high-income countries, where the rates range between 10.57 and 25.5, in countries such as Japan, France and Italy [31-34]. However, the rates are similar to those of Latin American countries, such as Brazil, Mexico and Ecuador where the incidence rates were 5.5, 2.4 and 3.7 per 100,000 population, respectively [8]. Mortality figures are similar: the average annual mortality rate in the US between 2010 and 2014 was 4.3 per 100,000 population, and it is estimated that 16,616 deaths will be attributed to primary malignant brain and other CNS tumors in the United States in 2018 (26). Similarly, Australia reported a crude death rate of 5.3 per 100,000 population [35]. On the contrary, a crude death rate of 3.6, 1.9 and 1.9 per 100,000 population was reported in Brazil, Mexico and Ecuador, respectively [8]. Standardized rates are similar between different cities, which gives even more credibility to their levels. The slightly lower level reported in Manizales, a relatively small city, may be due to diagnoses made outside the city, difficulty in registering all CNS tumors and, perhaps, to an underdiagnosis.

Pediatric and adult populations differ in terms of tumor characteristics. According to the literature, embryonal tumors and low-grade and high-grade glial lesions constitute the most common tumors in the pediatric population; it is worth mentioning that the frequency varies according to age subgroups [26]. This is consistent with our study, in which embryonal tumors (26%), astrocytomas (23.5%) and ependymomas (11.4), constituted the main histological subtypes within CNS tumors in this population. On the contrary, the retrospective study by *Paez et al* showed that in the pediatric population the most common primary CNS tumor was medulloblastoma [27]. *Chater-Cure et al* had similar findings, since in the

11 pediatric patients 3 medulloblastomas and 3 gliomas were found [28]. These two findings clearly demonstrate the great difference between data from case series and hospitals in particular, versus population-based data. The most common tumor location in the pediatric population was the supratentorial, temporoparietal lobe, which coincides with the literature [26].

The location of tumors in adults was similar to that of the pediatric population; the supratentorial location was even more predominant, with 92%. As for tumor histology, the fact that 30% of cases do not have

histology details complicates their interpretation. In cases with information on the histological subtype, the three main tumors in descending order were glial lesions (high-grade), meningiomas, and hematolymphoid tumors, but with much lower proportions than those reported in the literature. The fact that hematolymphoid tumors are among the 3 most common tumors differs from the literature, which reports sellar lesions (pituitary adenomas) within the 3 most common types of tumors. Usually, they are reported as follows: meningiomas (36.8%), followed by pituitary tumors (16.2%) and glioblastomas (14.9%). In the study by *Paez et al*, the most common primary tumors were gliomas, and of these the highest proportion was glioblastoma (17.9%), followed by meningioma (10.3%) [27]. Similarly, *Bray et al* reported in a population-based database that 62.1% of the nervous system tumors corresponded to neuroepithelial tumors, and within these, approximately 89% corresponded to gliomas, 10% to embryonal tumors, and less than 1% were classified as "Others" [5]. In the US registry of brain tumors, meningiomas were the most common, accounting for about 36.8% of tumors in general; of these, 79% were located in the brain meninges and 4.2% in the spinal meninges. On the other hand, glioblastoma was the third most commonly reported histological subtype; in general, it is the most common malignant tumor, and constitutes 14.9% of all primary brain tumors and 47.1% of malignant primary brain tumors [26].

It is remarkable that in this study, pituitary adenomas were not among the most common tumors, something that differs from what is reported in the literature, since pituitary tumors constitute the second most common primary nervous system tumor of in the adult population (16.2%), with an incidence of 3.98 per 100,000 people according to CBTRUS [26]. This is explained by the high percentage of tumors that are not classified by subtype, and perhaps by a underreporting in the databases or a subdiagnosis by the presence of patients with asymptomatic or intervened lesions.

## Limitations and future directions

In Colombia, there are very few reports on the epidemiology of brain tumors [19,27,36] and those that exist are from hospital records or specialized centers, which do not have a rigorous and massive registry or represent the entire population of patients, unlike European or US databases. In 5 of the 118 cities in our country there is a formal population-based cancer registry. In addition, these databases have general data that lack relevant details, such as specific characteristics in the follow-up and characterization in the histopathological diagnosis, among others. Another important limitation in our country is the difficult access to an integrated and uniform network system for registration in databases in the different cities [29,30,37]. Although the present study does not reflect the epidemiology of brain tumors throughout Colombia, given that the results obtained only represent some cities, we consider that the study gathers the most up-to-date and population-based data on brain tumors in Colombia. Since the incidence of CNS tumors does not normally show strong changes in its incidence or mortality, these data from the 2002-2012 period help us create tactics to improve decision making in this group of patients, and to implement public health strategies that allow planning preventive activities and clinical trials to improve the quality of medical care [20,38]. In addition, the results help us to visualize the current situation of the Colombian databases, in which histological and location data and other details are missing, such as the clinical stage

at the time of diagnosis. It would be important to work on achieving a sound and detailed registry that gathers the most important variables on brain tumors, to know the real epidemiology, which allows finding health system flaws to implement the necessary solutions.

## CONCLUSIONS

The present study is the most recent work on the characterization, epidemiology, incidence and mortality of brain tumors in Colombia from a 10-year period, whose statistics are low compared to what is reported in the literature. We consider that for future population studies it is essential to expand coverage and data collection in population-based cancer registries, which are necessary to implement health policies and strategies.

## Conflict of interest

All authors declare that they have no conflict of interest in relation to the publication of this manuscript.

## Acknowledgments

To SICC-infocancer and the population-based cancer registries in Colombia for their great cooperation in sending the anonymized databases. Without their help this article could not have been made.

#### Ready to submit your research? Choose Auctores and benefit from:

- ❖ fast, convenient online submission
- ❖ rigorous peer review by experienced research in your field
- ❖ rapid publication on acceptance
- ❖ authors retain copyrights
- ❖ unique DOI for all articles
- ❖ immediate, unrestricted online access

At Auctores, research is always in progress.
